Describing Quantitative Data

Graphical Methods

- Stem-and-leaf (small data set, no loss of information)
- Histogram (large data set)
- Time series plot

Numerical Measures

- Central Tendency: mean, median
- Variation: range, variance, standard deviation
- Relative Standing: percentile, z-score
**Stem-and-Leaf Display**

Steps to construct a stem-and-leaf display:

- Divide each observation into two parts: stem and leaf.
- List the stems in order in a column
- Place the leaf for each observation in the appropriate stem row. Arrange the leaves in each row in ascending order.

Stem-and-leaf Display for CPU time:

**Histogram**

Steps to construct histogram:

1. Calculate range of the data: \( \text{min(data)} - \text{max(data)} \)
2. Divide the range into classes (bins, intervals) of equal width. For the number of classes, refer to the following rule.

<table>
<thead>
<tr>
<th>Number of observations</th>
<th>Number of classes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 25</td>
<td>5 or 6</td>
</tr>
<tr>
<td>25-50</td>
<td>7-14</td>
</tr>
<tr>
<td>More than 50</td>
<td>15-20</td>
</tr>
</tbody>
</table>

3. For each class, calculate the class frequency, which is equal to the number of observations falling in that class.
4. Similarly, relative class frequency can be defined as
   \[
   \frac{\text{class frequency}}{\text{total number of observations}}
   \]
5. The histogram is a bar graph in which the categories are classes and the heights of the bars are determined by class frequency or relative class frequency.
Histogram for CPU data

- Because the bars are of equal width,
  \[ \text{Area of a bar} \sim \text{Class frequency} \sim \text{Relative class frequency}. \]

- The percentage of number of observations falling within a particular interval is proportional to the area of the bar above the interval.

- If we select one observation from the data, the likelihood (or probability) of that observation falling in a particular class (or interval) is proportional to the area of the bar above the interval.
**Shapes of Distribution**

Single Mode (mound-shaped)

Symmetric

Right skewed (long right tail)

Left skewed (long left tail)

**Time Series Plot**

Some data sets are **time series**, that is, measurements taken at regular intervals over time. Plots against time can reveal some important features of the data.

Time series plot of number of live births per 10,000 23-year-old women in the United States between 1917 and 1975:
**Numerical Descriptive Measures**

- **Central Tendency**
  - mean: average value
  - median: middle value

- **Variation**
  - range, IQR
  - variance (sample and population)
  - standard deviation

- **Relative Standing**
  - 100pth percentile: lower (or upper) quartile
  - z-score

---

**Term and Notation**

A **statistics** is a numerical descriptive measure computed from sample data.

A **parameter** is a numerical descriptive measure of a population.

Notation:

- Sample: \( y_1, y_2, \ldots, y_n \)
- Ordered Sample: \( y(1) \leq y(2) \leq \cdots \leq y(n) \)
**Location**

- Sample mean $\bar{y} = (\sum_{i=1}^{n} y_i)/n$ (population mean $\mu$)

- Sample median
  
  $$m(y) = \begin{cases} 
  y((n+1)/2) & \text{n odd} \\
  \frac{y(n/2)+y(n/2+1)}{2} & \text{n even}
  \end{cases}$$
  
  (Population median $\tau$)

- For symmetric distribution, the two are the same; For skewed distribution, the **mean** is located farther toward the long tail than the **median**.

- The **mean** is sensitive to large or small observations, while the **median** is resistant to the influence of extreme observations (i.e., *robust*).

**Variation**

- Range $= y(n) - y(1)$

- Sample variance
  
  $$s^2 = \frac{\sum_{i=1}^{n} (y_i - \bar{y})^2}{n-1}$$
  
  Population variance
  
  $$\sigma^2 = \frac{\sum_{i=1}^{n} y_i^2 - (\sum_{i=1}^{n} y_i)^2/n}{n-1}.$$ 

- Standard deviation $= \sqrt{\text{variance}}$. 
\[ s^2 = \frac{\sum(y_i - \bar{y})^2}{n - 1}. \]

Why \( n - 1 \)? Why not average in the usual way by dividing by \( n \)?

- If we knew the population mean \( \mu \), then we’d define the sample variance as
  \[ s^2 = \frac{\sum_{i=1}^{n}(y_i - \mu)^2}{n} \tag{*}. \]
- But we don’t know \( \mu \), so we estimate it by \( \bar{y} \).
- The total deviation \( \sum(y_i - \bar{y})^2 \) is smaller than \( \sum(y_i - \mu)^2 \) (why?), so just plugging in \( \bar{y} \) in the formula \( (*) \) will result in underestimating of the population variance.
- So we divide by \( n - 1 \) instead of \( n \). The reason why \( n - 1 \) is used instead of any other value less than \( n \), follows from the fact that there is a constraint on the \( n \) quantities \( y_i = \bar{y} \).
- Given any \( n - 1 \) of the \( y_i - \bar{y} \), one can solve for the omitted data value (\( n - 1 \) degree of freedom).

---

**Effect of Linear Transformation**

- Multiplying each observation by a number \( b \) multiplies measures of center (mean and median) by \( b \), and measures of variance (range and standard deviation) by \( |b| \).
- Adding the same number \( a \) to each observation adds \( a \) to location measure, but does not change measures of variation.
**Relative Standing**

**Percentile**

- The $100p$th percentile: a value so that $100p\%$ of data are smaller than it.

- the lower quartile $Q_L$, the mid-quartile and the upper quartile $Q_U$.
  
  Interquartile Range $IQR = Q_U - Q_L$

- Finding percentiles with small data set

  Calculate $l = p(n+1)/100$ and round to the nearest integer (if $l$ falls halfway between two integers, round up). Then $y(l)$ is the $p$th percentile.

- Note: By definition, percentiles are not unique and the outputs from different software may not be the same

**Standardizing Observations**

The **z-score** for a value $y$ of a data set is the distance that $y$ lies above or below the mean, measured in units of the standard deviation:

- **Sample z-score**: $z = (y - \bar{y})/s$
- **Population z-score**: $z = (y - \mu)/\sigma$

Let $z_i = z$-score of $y$, then $z_1, \ldots, z_n$ have mean 0, variance 1.
Normal Distribution

![Normal Distribution Graph](image)

**The Empirical Rule** (68-95-99.7 Rule)

For mound-shaped distribution

(1) Approximately 68% of the data will lie within 1 standard deviation of their mean

(2) Approximately 95% of the data will lie within 2 standard deviation of their mean

(3) almost all the data (99.7%) will lie within 3 standard deviation of their mean

---

**Detecting Outliers**

An observation $y$ that is unusually large or small relative to the other values in a data set is called an **outlier**.

Outlier $\neq$ Bad observation

**Rule of Thumb for detecting outliers**

- z-score greater than 3
- Boxplot: 1.5 IQL away from the median
Boxplot

Five-number summary: min, $Q_L$, median, $Q_U$ and max

Boxplot is a graph of five-number summary

(1) A box spans the quartile

(2) A line in the box marks the median

(3) Suspected outliers (more than 1.5IQR from the median) are plotted individually

(4) Lines extend from the box to the smallest and largest observations that are not suspected outliers

A fun example of using boxplot to compare distributions: The data set is from

The data is collected to answer the question: “Do blonds and brunettes have a different pain threshold?”.

<table>
<thead>
<tr>
<th>hair color</th>
<th>pain threshold score</th>
