Lecture 13 - ANOVA

Sta102 / BME102

Colin Rundel

March 17, 2014

Wolf River

- The Wolf River in Tennessee flows past an abandoned site once used by the pesticide industry for dumping wastes, including chlordane (pesticide), aldrin, and dieldrin (both insecticides).
- These highly toxic organic compounds can cause various cancers and birth defects.
- These compounds are denser than water and their molecules tend to become stuck in sediment, and are more likely to be found in higher concentrations near the bottom than near mid-depth.

Upcoming Due Dates, etc.

- Lab 8 is due in Lab tomorrow (3/18)
- Homework 7 is due in Lecture the day after tomorrow (3/19)
- Homework 8 will be due in Lecture next Monday (3/24)
- Midterm 2 is next Wednesday (3/26)
- Project stuff (More on Wednesday)
 - Project 1 due two weeks from Friday (4/04)
 - Project 2 Proposal due the following Friday (4/11)
 - Project 2 due at the Final (4/28)

Sta102 / BME102 (Colin Rundel)

Lec 13

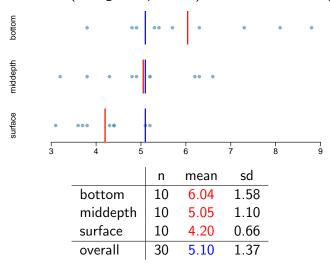

Wolf River - Data

Aldrin concentration (nanograms per liter) at three levels of depth.

	aldrin	depth
1	3.80	bottom
2	4.80	bottom
:	:	:
10	8.80	bottom
11	3.20	middepth
12	3.80	middepth
:	:	:
20	6.60	middepth
21	3.10	surface
22	3.60	surface
:	:	:
30	5.20	surface

Exploratory analysis

Aldrin concentration (nanograms per liter) at three levels of depth.

10\/A

Aldrin in the Wolf River

ANOVA

ANOVA is used to assess whether the mean of the outcome variable is different for different levels of a categorical variable.

 H_0 : The mean outcome is the same across all categories,

$$\mu_1 = \mu_2 = \dots = \mu_k,$$

where μ_i represents the mean of the outcome for observations in category i.

 H_A : At least one mean is different than others.

Note - this hypothesis test does not tell us if all the means are different or only if one pair is different, more on how to do that later.

Research question

Is there a difference between the mean aldrin concentrations among the three levels?

- To compare means of 2 groups we use a Z or a T statistic.
- To compare means of 3 or more groups we use a new test called ANOVA (analysis of variance) and a new test statistic, F.

Sta102 / BME102 (Colin Rundel)

Lec 13

March 17 2014 6 / 2

ANOV

Aldrin in the Wolf River

Conditions

- The observations should be independent within and between groups
 - If the data are a simple random sample from less than 10% of the population, this condition is satisfied.
 - Carefully consider whether the data may be independent (e.g. no pairing).
 - Always important, but sometimes difficult to check.
- The observations within each group should be nearly normal.
 - Particularly important when the sample sizes are small.

How do we check for normality?

- The variability across the groups should be about equal.
 - Particularly important when the sample sizes differ between groups.

How can we check this condition?

Sta102 / BME102 (Colin Rundel)

Lec 13

March 17 2014

Sta102 / BME102 (Colin Rundel)

Lec 13

March 17, 2014 8

(1) Independence

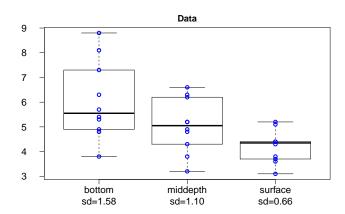

Does this condition appear to be satisfied for the Wolf River data?

Sta102 / BME102 (Colin Rundel)

Lec 13

Constant variance

Does this condition appear to be satisfied?

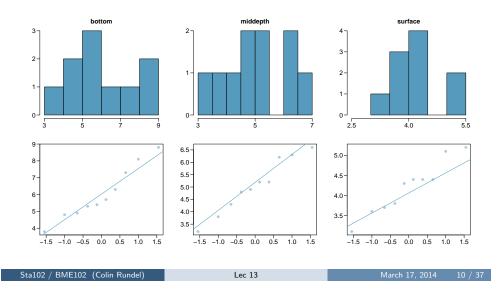

In this case it is somewhat hard to tell since the means are different.

Checking conditions

(2) Approximately normal

Does this condition appear to be satisfied?

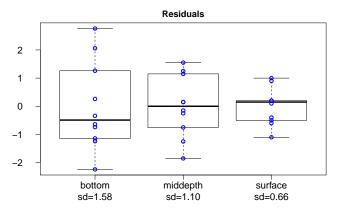

ANOVA Checking conditions

Constant variance - Residuals

One of the ways to think about each data point is as follows:

$$y_{ij} = \mu_i + \epsilon_{ij}$$

where ϵ_{ij} is called the residual $(\epsilon_{ij} = y_{ij} - \mu_i)$.

Sta102 / BME102 (Colin Rundel)

Lec 13

z/t test vs. ANOVA - Purpose

z/t test

Compare means from *two* groups to see whether they are so far apart that the observed difference cannot reasonably be attributed to sampling variability.

$$H_0: \mu_1 = \mu_2$$

ANOVA

Compare the means from *two or* more groups to see whether they are so far apart that the observed differences cannot all reasonably be attributed to sampling variability.

$$H_0: \mu_1 = \mu_2 = \cdots = \mu_k$$

Sta102 / BME102 (Colin Rundel) Lec 13 March

ANOVA

Comparison

z/t test vs. ANOVA

- With only two groups t-test and ANOVA are equivalent, but only if we use a pooled standard variance in the denominator of the test statistic.
- With more than two groups, ANOVA compares the sample means to an overall *grand mean*.

z/t test vs. ANOVA - Method

z/t test

Compute a test statistic (a ratio).

$$z/t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{SE(\bar{x}_1 - \bar{x}_2)}$$

ANOVA

Compute a test statistic (a ratio).

$$F = \frac{\text{variability btw. groups}}{\text{variability w/in groups}}$$

- Large test statistics lead to small p-values.
- If the p-value is small enough H_0 is rejected, and we conclude that the population means are not equal.

Sta102 / BME102 (Colin Rundel)

Lec 13

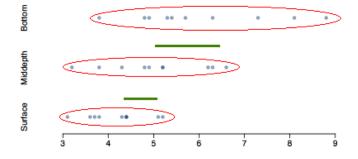

March 17 2014 1

ANOVA and the F t

Test statistic

Does there appear to be a lot of variability within groups? How about between groups?

$$F = \frac{\text{variability btw. groups}}{\text{variability w/in groups}}$$

Test statistic (cont.)

$$F = \frac{\text{variability btw. groups}}{\text{variability w/in groups}} = \frac{MSG}{MSE}$$

• *MSG* is mean square between groups

$$df_G = k - 1$$

where k is number of groups

• MSE is mean square error - variability in residuals

$$df_E = n - k$$

where n is number of observations.

Sta102 / BME102 (Colin Rundel)

Lec 13

Sta102 / BME102 (Colin Rundel)

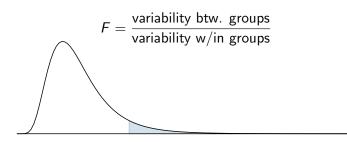

ANOVA output

		Df	Sum Sq	Mean Sq	F value	Pr(>F)
(Group)	depth	2	16.96	8.48	6.13	0.0063
(Error)	Residuals	27	37.33	1.38		
	<i>T</i> otal	29	54.29			

Degrees of freedom associated with ANOVA

- groups: $df_G = k 1$, where k is the number of groups
- total: $df_T = n 1$, where n is the total sample size
- error: $df_F = df_T df_G$
- $df_G = k 1 = 3 1 = 2$
- $df_T = n 1 = 30 1 = 29$
- $df_E = 29 2 = 27$

F distribution and p-value

- In order to be able to reject H_0 , we need a small p-value, which requires a large F statistic.
- In order to obtain a large F statistic, variability between sample means needs to be greater than variability within sample means.

ANOVA output (cont.)

		Df	Sum Sq	Mean Sq	F value	Pr(>F)
(Group)	depth	2	16.96	8.48	6.13	0.0063
(Error)	Residuals	27	37.33	1.38		
	<i>T</i> otal	29	54.29			

Sum of squares between groups, SSG

Measures the variability between groups

$$SSG = \sum_{i=1}^k n_i (\bar{x}_i - \bar{x})^2$$

where n_i is each group size, \bar{x}_i is the average for each group, \bar{x} is the overall (grand)

	n	mean
bottom	10	6.04
middepth	10	5.05
surface	10	4.2
overall	30	5.1
middepth surface	10 10	5.05 4.2

$$SSG = (10 \times (6.04 - 5.1)^{2}) + (10 \times (5.05 - 5.1)^{2}) + (10 \times (4.2 - 5.1)^{2})$$
$$= 16.96$$

Mean Sq

ANOVA output (cont.) - SST

		Df	Sum Sq	Mean Sq	F value	Pr(>F)
(Group)	depth	2	16.96	8.48	6.13	0.0063
(Error)	Residuals	27	37.33	1.38		
	<i>T</i> otal	29	54.29			

Sum of squares total, SST

Measures the variability between groups

$$SST = \sum_{i=1}^{n} (x_i - \bar{x})^2$$

where x_i represent each observation in the dataset.

$$SST = (3.8 - 5.1)^{2} + (4.8 - 5.1)^{2} + (4.9 - 5.1)^{2} + \dots + (5.2 - 5.1)^{2}$$

$$= (-1.3)^{2} + (-0.3)^{2} + (-0.2)^{2} + \dots + (0.1)^{2}$$

$$= 1.69 + 0.09 + 0.04 + \dots + 0.01$$

$$= 54.29$$

Sta102 / BME102 (Colin Rundel)

Sum of squares error, SSE

(Group)

(Error)

Measures the variability within groups:

ANOVA output (cont.) - SSE

depth

Total

Residuals

27

29

$$SSE = SST - SSG$$

Sum Sq

16.96

37.33

54.29

$$SSE = 54.29 - 16.96 = 37.33$$

Sta102 / BME102 (Colin Rundel)

ANOVA output (cont.) - MS

		Df	Sum Sq	Mean Sq	F value	Pr(>F)
(Group)	depth	2	16.96	8.48	6.13	0.0063
(Error)	Residuals	27	37.33	1.38		
	<i>T</i> otal	29	54.29			

Mean square

Mean square is calculated as sum of squares divided by the degrees of freedom.

$$MSG = 16.96/2 = 8.48$$

 $MSE = 37.33/27 = 1.38$

ANOVA output (cont.) - F

		Df	Sum Sq	Mean Sq	F value	Pr(>F)
(Group)	depth	2	16.96	8.48	6.14	0.0063
(Error)	Residuals	27	37.33	1.38		
	<i>T</i> otal	29	54.29			

Test statistic, F value

As we discussed before, the F statistic is the ratio of the between group and within group variability.

$$F = \frac{MSG}{MSE}$$

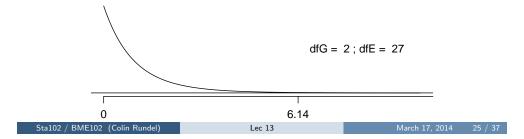

$$F = \frac{8.48}{1.38} = 6.14$$

ANOVA output (cont.) - P-value

		Df	Sum Sq	Mean Sq	F value	Pr(>F)
(Group)	depth	2	16.96	8.48	6.14	0.0063
(Error)	Residuals	27	37.33	1.38		
	<i>T</i> otal	29	54.29			

P-value

The probability of at least as large a ratio between the "between group" and "within group" variability, if in fact the means of all groups are equal. It's calculated as the area under the F curve, with degrees of freedom df_G and df_E , above the observed F statistic.

Conclusion

- If p-value is small (less than α), reject H_0 . The data provide convincing evidence that at least one mean is different from (but we can't tell which one).
- If p-value is large, fail to reject H_0 . The data do not provide convincing evidence that at least one pair of means are different from each other, the observed differences in sample means are attributable to sampling variability (or chance).

What is the conclusion of the hypothesis test for Wolf river?

Conclusion - in context

Lec 13 Sta102 / BME102 (Colin Rundel)

Multiple comparisons

Multiple comparisons & Type 1 error rate

Which means differ?

- We've concluded that at least one pair of means differ. The natural question that follows is "which ones?"
- ullet We can do two sample t tests for differences in each possible pair of groups.

Can you see any pitfalls with this approach?

- When we run too many tests, the Type 1 Error rate increases.
- This issue is resolved by using a modified significance level.

Sta102 / BME102 (Colin Rundel

Multiple comparisons & Type 1 error rate

In the aldrin data set depth has 3 levels: bottom, mid-depth, and surface.

If $\alpha = 0.05$, what should be the modified significance level or two sample t tests for determining which pairs of groups have significantly different

Multiple comparisons

- The scenario of testing many pairs of groups is called *multiple* comparisons.
- If there are k groups, then there are $K = \binom{k}{2} = \frac{k(k-1)}{2}$ possible pairs.
- One common approach is the *Bonferroni correction* that uses a more stringent significance level for each test:

$$\alpha^* = \alpha/K$$

where K is the number of comparisons being considered.

Sta102 / BME102 (Colin Rundel

Lec 13

means?

Multiple comparisons & Type 1 error rate

Clicker Question - Which means differ?

Based on the box plots below, which means would you expect to be significantly different?

- (a) bottom & surface
- (b) bottom & mid-depth
- (c) mid-depth & surface
- (d) bottom & mid-depth; mid-depth & surface
- (e) bottom & mid-depth; bottom & surface: mid-depth & surface

Multiple comparisons

Multiple comparisons & Type 1 error rate

Which means differ? (cont.)

Determining the modified α

If the ANOVA assumption of equal variability across groups is satisfied, we can use the data from all groups to estimate variability:

- Estimate any within-group standard deviation with \sqrt{MSE} , which is Spooled
- Use the error degrees of freedom, n k, for t-distributions

Difference in two means: after ANOVA

$$SE = \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} \approx \sqrt{\frac{MSE}{n_1} + \frac{MSE}{n_2}}$$

Multiple comparisons & Type 1 error rate

Practice Problem

OpenIntro Statistics - 5.40

Previously we have seen data from the General Social Survey in order to compare the average number of hours worked per week by US residents with and without a college degree. However, this analysis didn't take advantage of the original data which contained more accurate information on educational attainment (less than high school, high school, junior college, Bachelor's, and graduate school).

Using ANOVA, we can consider educational attainment levels for all 1,172 respondents at once instead of re-categorizing them into two groups. On the following slide are the distributions of hours worked by educational attainment and relevant summary statistics that will be helpful in carrying out this analysis.

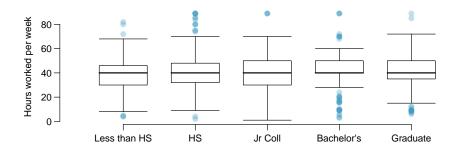

bottom and at surface?
