

# Lecture 18 - Regression: Inference, Outliers, and Intervals

---

Sta 102

June 10, 2016

Colin Rundel & Mine Çetinkaya-Rundel

## Types of outliers in linear regression

---

## Types of outliers

Is regression robust? Think about how the regression line would change with and without “outlier(s)”.

# Types of outliers

How does the following point influence the least squares line?

# Types of outliers

How does the following point influence the least squares line?

Without the outlier there is *no* relationship between  $X$  and  $Y$  ( $\text{Cor}(X, Y) = 0$ ).

# Types of outliers

How does the following point influence the least squares line?

What would have happened if the outlier was directly above the other points?

# With and without

$$R = 0.72, R^2 = 0.522$$

$$R = -0.091, R^2 = 0.0083$$

## Some terminology

*Outliers* are points that fall away from the main body of other points - but not all outliers are created equal.

## Some terminology

*Outliers* are points that fall away from the main body of other points - but not all outliers are created equal.

- Outliers that are horizontally distant from the body of other points are called *leverage* points.

## Some terminology

*Outliers* are points that fall away from the main body of other points - but not all outliers are created equal.

- Outliers that are horizontally distant from the body of other points are called *leverage* points.
- Points with high leverage that actually influence the *slope* of the regression line are called *influential* points.

## Some terminology

*Outliers* are points that fall away from the main body of other points - but not all outliers are created equal.

- Outliers that are horizontally distant from the body of other points are called *leverage* points.
- Points with high leverage that actually influence the *slope* of the regression line are called *influential* points.
- In order to determine if a point is influential, visualize the regression line with and without the point. Does the slope of the line change considerably? If so, then the point is influential.

# Influential points

Data are available on the log of the surface temperature and the log of the light intensity of 47 stars in the star cluster CYG OB1.

# Hertzprung-Russell Diagram

# Types of outliers

Which type of outlier is displayed below?

# Types of outliers

Which type of outlier is displayed below?

## Recap

Are following statements true or false?

- (1) Influential points always change the intercept of the regression line.
- (2) Influential points always reduce  $R^2$ .
- (3) It is much more likely for a high leverage point to be influential, than a low leverage point.
- (4) When the data set includes an influential point, the relationship between the explanatory variable and the response variable is always nonlinear.

## Recap

Are following statements true or false?

- (1) Influential points always change the intercept of the regression line. *False*
- (2) Influential points always reduce  $R^2$ .
- (3) It is much more likely for a high leverage point to be influential, than a low leverage point.
- (4) When the data set includes an influential point, the relationship between the explanatory variable and the response variable is always nonlinear.

## Recap

Are following statements true or false?

- (1) Influential points always change the intercept of the regression line. *False*
- (2) Influential points always reduce  $R^2$ . *False*
- (3) It is much more likely for a high leverage point to be influential, than a low leverage point.
- (4) When the data set includes an influential point, the relationship between the explanatory variable and the response variable is always nonlinear.

## Recap

Are following statements true or false?

- (1) Influential points always change the intercept of the regression line. *False*
- (2) Influential points always reduce  $R^2$ . *False*
- (3) It is much more likely for a high leverage point to be influential, than a low leverage point. *True*
- (4) When the data set includes an influential point, the relationship between the explanatory variable and the response variable is always nonlinear.

## Recap

Are following statements true or false?

- (1) Influential points always change the intercept of the regression line. *False*
- (2) Influential points always reduce  $R^2$ . *False*
- (3) It is much more likely for a high leverage point to be influential, than a low leverage point. *True*
- (4) When the data set includes an influential point, the relationship between the explanatory variable and the response variable is always nonlinear. *False*

## Inference for linear regression

---

## Nature vs. nurture?

In 1966 Cyril Burt published a paper called “The genetic determination of differences in intelligence: A study of monozygotic twins reared apart” The data consist of IQ scores for [an assumed random sample of] 27 identical twins, one raised by foster parents, the other by the biological parents.

## Finding the regression line

	Foster IQ (y)	Biological IQ (x)
mean	$\bar{y} = 95.11$	$\bar{x} = 95.30$
sd	$s_y = 16.08$	$s_x = 15.73$
correlation	$R = 0.8819$	

## Finding the regression line

	Foster IQ (y)	Biological IQ (x)
mean	$\bar{y} = 95.11$	$\bar{x} = 95.30$
sd	$s_y = 16.08$	$s_x = 15.73$
correlation	$R = 0.8819$	

$$b_1 = \frac{s_y}{s_x} R = \frac{16.08}{15.73} 0.8819 = 0.90$$

## Finding the regression line

	Foster IQ (y)	Biological IQ (x)
mean	$\bar{y} = 95.11$	$\bar{x} = 95.30$
sd	$s_y = 16.08$	$s_x = 15.73$
correlation	$R = 0.8819$	

$$b_1 = \frac{s_y}{s_x} R = \frac{16.08}{15.73} 0.8819 = 0.90$$

$$b_0 = \bar{y} - b_1 \bar{x} = 95.11 - 0.90 \cdot 95.30 = 9.2$$

# Regression Output

## Conditions for inference

In order to conduct *inference*, the following conditions must be met:

1. Linearity
2. Nearly normal residuals
3. Constant variability

## Conditions: (1) Linearity

- The relationship between the explanatory and the response variable should be linear.

## Conditions: (1) Linearity

- The relationship between the explanatory and the response variable should be linear.
- Methods for fitting a model to non-linear relationships exist, but are beyond the scope of this class.

## Conditions: (1) Linearity

- The relationship between the explanatory and the response variable should be linear.
- Methods for fitting a model to non-linear relationships exist, but are beyond the scope of this class.
- Check using a *scatterplot* (x vs y) or a *residual plot* (x vs resid) .

## Conditions: (2) Nearly normal residuals

- The residuals should follow a nearly normal distribution.

## Conditions: (2) Nearly normal residuals

- The residuals should follow a nearly normal distribution.
- This condition may not be satisfied when there are unusual observations that don't follow the trend of the rest of the data.

## Conditions: (2) Nearly normal residuals

- The residuals should follow a nearly normal distribution.
- This condition may not be satisfied when there are unusual observations that don't follow the trend of the rest of the data.
- Checked using a histogram or normal probability plot of residuals.

## Conditions: (2) Nearly normal residuals

- The residuals should follow a nearly normal distribution.
- This condition may not be satisfied when there are unusual observations that don't follow the trend of the rest of the data.
- Checked using a histogram or normal probability plot of residuals.

## Conditions: (3) Constant variability

- The variability of the residuals from the least squares line should be constant.

## Conditions: (3) Constant variability

- The variability of the residuals from the least squares line should be constant.
- This implies that the variability of *any* region of the residual plot should be the same as any other region.

## Conditions: (3) Constant variability

- The variability of the residuals from the least squares line should be constant.
- This implies that the variability of *any* region of the residual plot should be the same as any other region.
- Also referred to as *homoscedasticity* / *heteroscedasticity*.

## Conditions: (3) Constant variability

- The variability of the residuals from the least squares line should be constant.
- This implies that the variability of *any* region of the residual plot should be the same as any other region.
- Also referred to as *homoscedasticity* / *heteroscedasticity*.
- Check using a residuals plot.

# Checking conditions

What condition is this linear model violating?

## Checking conditions (II)

What condition is this linear model obviously violating?

## Back to Nature vs nurture

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
biolIQ	0.9014	0.0963	9.36	0.0000

## Testing for the slope

Assuming that these 27 twins comprise a representative sample of all twins separated at birth, we would like to test if these data provide convincing evidence that the IQ of the biological twin is a significant predictor of IQ of the foster twin.

## Testing for the slope

Assuming that these 27 twins comprise a representative sample of all twins separated at birth, we would like to test if these data provide convincing evidence that the IQ of the biological twin is a significant predictor of IQ of the foster twin.

What are the appropriate hypotheses?

## Testing for the slope

Assuming that these 27 twins comprise a representative sample of all twins separated at birth, we would like to test if these data provide convincing evidence that the IQ of the biological twin is a significant predictor of IQ of the foster twin.

What are the appropriate hypotheses?

First consider what the null hypothesis should be, if there is no relationship between the two variables what value of the slope would we expect to see?

## Testing for the slope

Assuming that these 27 twins comprise a representative sample of all twins separated at birth, we would like to test if these data provide convincing evidence that the IQ of the biological twin is a significant predictor of IQ of the foster twin.

What are the appropriate hypotheses?

First consider what the null hypothesis should be, if there is no relationship between the two variables what value of the slope would we expect to see?

$$H_0: \beta_1 = 0$$

$$H_A: \beta_1 \neq 0$$

## Testing for the slope (cont.)

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

## Testing for the slope (cont.)

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

We are interested in inference on  $\beta_1$  which we estimate using the point estimate  $b_1$ .

It turns out that after normalizing our point estimate has a  $T$  distribution with  $n - 2$  degrees of freedom.

$$T_{df=n-2} = \frac{b_1 - \beta_1}{SE}$$

where,

$$SE_{b_1} = \frac{1}{\sqrt{n-1}} \frac{s_e}{s_x} = \frac{1}{\sqrt{n-1}} \frac{\sqrt{\frac{1}{n-2} \sum_{i=1}^n \epsilon_i^2}}{\sqrt{\frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2}}$$

## Data + Regression Output

	Foster IQ (y)	Biological IQ (x)
mean	$\bar{y} = 95.11$	$\bar{x} = 95.30$
sd	$s_y = 16.08$	$s_x = 15.73$
n = 27	$R = 0.8819$	

## Coefficients:

```

## Testing for the slope (cont.)

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	<i>0.9014</i>	<i>0.0963</i>	<i>9.36</i>	<i>0.0000</i>

## Testing for the slope (cont.)

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

$$T = \frac{0.9014 - 0}{0.0963} = 9.36$$

## Testing for the slope (cont.)

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

$$T = \frac{0.9014 - 0}{0.0963} = 9.36$$
$$df = 27 - 2 = 25$$

## Testing for the slope (cont.)

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

$$T = \frac{0.9014 - 0}{0.0963} = 9.36$$

$$df = 27 - 2 = 25$$

$$\text{p-value} = P(|t| > 9.36) < 0.01$$

## Confidence interval for the slope

Since we know the sampling distribution we can also construct a confidence interval:  $point\ estimate \pm CV \times SE$ .

What is the correct 95% confidence interval for the slope parameter?

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

## Confidence interval for the slope

Since we know the sampling distribution we can also construct a confidence interval:  $point\ estimate \pm CV \times SE$ .

What is the correct 95% confidence interval for the slope parameter?

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

$$n = 27 \quad df = 27 - 2 = 25 \quad t_{25}^* = 2.06$$

## Confidence interval for the slope

Since we know the sampling distribution we can also construct a confidence interval:  $point\ estimate \pm CV \times SE$ .

What is the correct 95% confidence interval for the slope parameter?

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.2076	9.2999	0.99	0.3316
bioIQ	0.9014	0.0963	9.36	0.0000

$$n = 27 \quad df = 27 - 2 = 25 \quad t_{25}^* = 2.06$$

$$\begin{aligned} 95\% CI &= PE \pm CV \times SE \\ &= 0.9014 \pm 2.06 \times 0.0963 \\ &= (0.7, 1.1) \end{aligned}$$

## Recap

Inference for the slope for a SLR model (only one explanatory variable):

## Recap

Inference for the slope for a SLR model (only one explanatory variable):

- Hypothesis test for  $\beta_1$ :

$$T = \frac{b_1 - \beta_1}{SE_{b_1}} \quad df = n - 2$$

## Recap

Inference for the slope for a SLR model (only one explanatory variable):

- Hypothesis test for  $\beta_1$ :

$$T = \frac{b_1 - \beta_1}{SE_{b_1}} \quad df = n - 2$$

- Confidence interval for  $\beta_1$ :

$$b_1 \pm t_{df=n-2}^* \times SE_{b_1}$$

## Recap

Inference for the slope for a SLR model (only one explanatory variable):

- Hypothesis test for  $\beta_1$ :

$$T = \frac{b_1 - \beta_1}{SE_{b_1}} \quad df = n - 2$$

- Confidence interval for  $\beta_1$ :

$$b_1 \pm t_{df=n-2}^* \times SE_{b_1}$$

- The regression output gives  $b_1$ ,  $SE_{b_1}$ , and the *two-tailed* p-value for the  $t$ -test of the slope when the null hypothesis is  $\beta_1 = 0$ .

## Caution

- Always be aware of the type of data you're working with: random sample, non-random sample, or population.

## Caution

- Always be aware of the type of data you're working with: random sample, non-random sample, or population.
- Statistical inference, and the resulting p-values, are meaningless when you have population data.

## Caution

- Always be aware of the type of data you're working with: random sample, non-random sample, or population.
- Statistical inference, and the resulting p-values, are meaningless when you have population data.
- If you have a sample that is non-random (biased), the results will be unreliable.

## Caution

- Always be aware of the type of data you're working with: random sample, non-random sample, or population.
- Statistical inference, and the resulting p-values, are meaningless when you have population data.
- If you have a sample that is non-random (biased), the results will be unreliable.
- The ultimate goal is to have independent observations – and you know how to check for those by now.

## Variability partitioning

- We considered the  $t$ -test as a way to evaluate the strength of evidence for a hypothesis test for the slope of relationship between  $x$  and  $y$ .

## Variability partitioning

- We considered the  $t$ -test as a way to evaluate the strength of evidence for a hypothesis test for the slope of relationship between  $x$  and  $y$ .
- However, we can also consider the variability in  $y$  explained by  $x$ , compared to the unexplained variability.

## Variability partitioning

- We considered the  $t$ -test as a way to evaluate the strength of evidence for a hypothesis test for the slope of relationship between  $x$  and  $y$ .
- However, we can also consider the variability in  $y$  explained by  $x$ , compared to the unexplained variability.
- *Partitioning* the variability in  $y$  to explained and unexplained variability is something we have already done (*ANOVA*).

## Sums of Squares

$$\sum_i (y_i - \bar{y})^2 = \sum_i (\hat{y}_i - \bar{y})^2 + \sum_i (y_i - \hat{y}_i)^2$$

ANOVA Model:

$$\hat{y}_{ij} = \bar{y}_i$$

$$SST = \sum_i \sum_j (y_{ij} - \bar{y})^2$$

$$SSG = \sum_i \sum_j (\bar{y}_i - \bar{y})^2$$

$$SSE = \sum_i \sum_j (y_i - \bar{y}_i)^2$$

# Sums of Squares

$$\sum_i (y_i - \bar{y})^2 = \sum_i (\hat{y}_i - \bar{y})^2 + \sum_i (y_i - \hat{y}_i)^2$$

ANOVA Model:

$$\hat{y}_{ij} = \bar{y}_i$$

$$SST = \sum_i \sum_j (y_{ij} - \bar{y})^2$$

$$SSG = \sum_i \sum_j (\bar{y}_i - \bar{y})^2$$

$$SSE = \sum_i \sum_j (y_i - \bar{y}_i)^2$$

Regression Model:

$$\hat{y}_i = b_0 + b_1 x_i$$

$$SST = \sum_i (y_i - \bar{y})^2$$

$$SSG = \sum_i (b_0 + b_1 x_i - \bar{y})^2$$

$$SSE = \sum_i (y_i - b_0 - b_1 x_i)^2$$

## ANOVA Table - Linear Regression

$$\text{F-statistic: } F_{1,25} = \frac{MS_{Reg}}{MS_{Err}} = 87.56 \quad (\text{ratio of explained to unexplained variability})$$

This test compares our regression model to an intercept *only* model - which is equivalent to a null hypothesis of  $\beta_1 = 0$  and the alternative of  $\beta_1 \neq 0$ .

$$\begin{aligned}R^2 &= \frac{\text{explained variability}}{\text{total variability}} = \frac{SS_{Reg}}{SS_{Tot}} = \frac{5231.13}{6724.66} = 0.7779 \\ &= 1 - \frac{SS_{Err}}{SS_{Tot}} = 1 - \frac{1493.53}{6724.66} = 0.7779 = (0.8820)^2\end{aligned}$$

# Confidence intervals and Prediction intervals

---

## Sampling Distribution of $\hat{y}$

One of the nice features of regression is that it provides a model which allows for prediction - one obvious question about any prediction is how confident are we about it, and what is the range of plausible values it might also take?

First we want to rewrite our model that it is in terms of just  $b_1$ :

$$\begin{aligned}\hat{y}_* &= b_0 + b_1 x_* \\ &= (\bar{y} - b_1 \bar{x}) + b_1 x_* \\ &= \bar{y} + b_1(x_* - \bar{x})\end{aligned}$$

It turns out that the sampling distribution of  $\hat{y}_*$  is Normal, so fully characterize the distribution we then need to know  $E(\hat{y}_*)$  and  $Var(\hat{y}_*)$ .

## Expected value of $\hat{y}$

We'll use the original definition of  $\hat{y} = b_0 + b_1 x_*$  here,

$$\begin{aligned} E(\hat{y}_*) &= E(b_0 + b_1 x_*) \\ &= E(b_0) + E(b_1 x_*) \\ &= \beta_0 + E(b_1) x_* \\ &= \beta_0 + \beta_1 x_* \end{aligned}$$

This assumes that both  $b_0$  and  $b_1$  are unbiased estimators of  $\beta_0$  and  $\beta_1$  respectively (which is true).

## Variance of $\hat{y}$

We'll use the revised definition of  $\hat{y} = \bar{y} + b_1(x_* - \bar{x})$  here,

$$\begin{aligned}\text{Var}(\hat{y}_*) &= \text{Var}(\bar{y} + b_1(x_* - \bar{x})) \\ &= \text{Var}(\bar{y}) + (x_* - \bar{x})^2 \text{Var}(b_1) \\ &= \frac{\sigma_e^2}{n} + (x_* - \bar{x})^2 \frac{\sigma_e^2}{\sum_i (x_i - \bar{x})^2} \\ &= \sigma_e^2 \left( \frac{1}{n} + \frac{(x_* - \bar{x})^2}{\sum_i (x_i - \bar{x})^2} \right)\end{aligned}$$

Since we don't know  $\sigma_e^2$  we need to use  $s_e^2$ , which means that we need to use a  $t$ -distribution for our sampling distribution.

## Confidence intervals for average values

A confidence interval for the average (expected) value of  $y$  for a given  $x^*$ , is given by

$$\hat{y} \pm t_{n-2}^* s_e \sqrt{\frac{1}{n} + \frac{(x^* - \bar{x})^2}{\sum_i (x_i - \bar{x})^2}}$$

where  $s_e$  is the standard deviation of the residuals

$$s_e = \sqrt{\frac{\sum (y_i - \hat{y}_i)^2}{n - 2}}$$

## Confidence intervals for average values

A confidence interval for the average (expected) value of  $y$  for a given  $x^*$ , is given by

$$\hat{y} \pm t_{n-2}^* s_e \sqrt{\frac{1}{n} + \frac{(x^* - \bar{x})^2}{\sum_i (x_i - \bar{x})^2}}$$

where  $s_e$  is the standard deviation of the residuals

$$s_e = \sqrt{\frac{\sum (y_i - \hat{y}_i)^2}{n - 2}}$$

Note that when  $x^* = \bar{x}$  this reduces to

$$\hat{y} \pm t_{n-2}^* \frac{s_e}{\sqrt{n}}$$

## Example Calculation

Calculate a 95% confidence interval for the average IQ score of foster twins whose biological twins have IQ scores of 100 points. Note that the average IQ score of 27 biological twins in the sample is 95.3 points, with a standard deviation is 15.74 points.

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	9.20760	9.29990	0.990	0.332
bioIQ	0.90144	0.09633	9.358	1.2e-09

Residual standard error: 7.729 on 25 degrees of freedom

## Example Calculation

Calculate a 95% confidence interval for the average IQ score of foster twins whose biological twins have IQ scores of 100 points. Note that the average IQ score of 27 biological twins in the sample is 95.3 points, with a standard deviation is 15.74 points.

	Estimate	Std. Error	t value	Pr(> t )

$$ME = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(100 - 95.3)^2}{26 \times 15.74^2}}$$

$$\approx 3.2$$

$$CI = 99.35 \pm 3.2$$

## Distance from the mean

How would you expect the width of the 95% confidence interval for the average IQ score of foster twins whose biological twins have IQ scores of 130 points ( $x^* = 130$ ) to compare to the previous confidence interval (where  $x^* = 100$ )?

How do the confidence intervals where  $x^* = 100$  and  $x^* = 130$  compare in terms of their widths?

$$x^* = 100 \quad ME_{100} = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(100 - 95.3)^2}{26 \times 15.74^2}} =$$

How do the confidence intervals where  $x^* = 100$  and  $x^* = 130$  compare in terms of their widths?

$$x^* = 100 \quad ME_{100} = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(100 - 95.3)^2}{26 \times 15.74^2}} =$$

$$x^* = 130 \quad ME_{130} = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(130 - 95.3)^2}{26 \times 15.74^2}} =$$

How do the confidence intervals where  $x^* = 100$  and  $x^* = 130$  compare in terms of their widths?

$$x^* = 100 \quad ME_{100} = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(100 - 95.3)^2}{26 \times 15.74^2}} = 3.2$$

$$x^* = 130 \quad ME_{130} = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(130 - 95.3)^2}{26 \times 15.74^2}} = 7.53$$

How do the confidence intervals where  $x^* = 100$  and  $x^* = 130$  compare in terms of their widths?

$$x^* = 100 \quad ME_{100} = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(100 - 95.3)^2}{26 \times 15.74^2}} = 3.2$$

$$x^* = 130 \quad ME_{130} = 2.06 \times 7.729 \times \sqrt{\frac{1}{27} + \frac{(130 - 95.3)^2}{26 \times 15.74^2}} = 7.53$$

## Recap

The width of the confidence interval for  $E(y)$  increases as  $x^*$  moves away from the center.

- Conceptually: We are much more certain of our predictions at the center of the data than at the edges (and our level of certainty decreases even further when predicting outside the range of the data – extrapolation).
- Mathematically: As  $(x^* - \bar{x})^2$  term increases, the margin of error of the confidence interval increases as well.

## Predicting a value, not an average

Earlier we learned how to calculate a confidence interval for average  $y$ ,  $E(y)$ , for a given  $x^*$ .

Suppose that we are not interested in the average, but instead we want to predict a future value of  $y$  for a given  $x^*$ .

Would you expect there to be more uncertainty around an average or a specific predicted value?

## Prediction intervals

A *prediction interval* for  $y$  for a given  $x^*$  is

$$\hat{y} \pm t_{n-2}^* s_e \sqrt{1 + \frac{1}{n} + \frac{(x^* - \bar{x})^2}{\sum_i (x_i - \bar{x})^2}}$$

where  $s$  is the standard deviation of the residuals.

## Prediction intervals

A *prediction interval* for  $y$  for a given  $x^*$  is

$$\hat{y} \pm t_{n-2}^* s_e \sqrt{1 + \frac{1}{n} + \frac{(x^* - \bar{x})^2}{\sum_i (x_i - \bar{x})^2}}$$

where  $s$  is the standard deviation of the residuals.

- The formula is very similar, except the variability is higher since there is a 1 added in the formula.

## Prediction intervals

A *prediction interval* for  $y$  for a given  $x^*$  is

$$\hat{y} \pm t_{n-2}^* s_e \sqrt{1 + \frac{1}{n} + \frac{(x^* - \bar{x})^2}{\sum_i (x_i - \bar{x})^2}}$$

where  $s$  is the standard deviation of the residuals.

- The formula is very similar, except the variability is higher since there is a 1 added in the formula.
- Prediction level: If we repeat the study of obtaining a regression data set many times, each time forming a XX% prediction interval at  $x^*$ , and wait to see what the future value of  $y$  is at  $x^*$ , then roughly XX% of the prediction intervals will contain the corresponding actual value of  $y$ .

## Confidence interval for $E(y)$ vs. prediction interval for $y$

## CI for $E(y)$ vs. PI for $y$

## CI for $E(y)$ vs. PI for $y$ - differences

A prediction interval is similar in spirit to a confidence interval, except that

## CI for $E(y)$ vs. PI for $y$ - differences

A prediction interval is similar in spirit to a confidence interval, except that

- the prediction interval is designed to cover a “moving target”, the random future value of  $y$

## CI for $E(y)$ vs. PI for $y$ - differences

A prediction interval is similar in spirit to a confidence interval, except that

- the prediction interval is designed to cover a “moving target”, the random future value of  $y$
- the confidence interval is designed to cover the “fixed target”, the average (expected) value of  $y$ ,  $E(y)$ ,

## CI for $E(y)$ vs. PI for $y$ - differences

A prediction interval is similar in spirit to a confidence interval, except that

- the prediction interval is designed to cover a “moving target”, the random future value of  $y$
- the confidence interval is designed to cover the “fixed target”, the average (expected) value of  $y$ ,  $E(y)$ ,

Although both are centered at  $\hat{y}$ , the prediction interval is wider than the confidence interval, for a given  $x^*$  and confidence level. This makes sense, since

## CI for $E(y)$ vs. PI for $y$ - differences

A prediction interval is similar in spirit to a confidence interval, except that

- the prediction interval is designed to cover a “moving target”, the random future value of  $y$
- the confidence interval is designed to cover the “fixed target”, the average (expected) value of  $y$ ,  $E(y)$ ,

Although both are centered at  $\hat{y}$ , the prediction interval is wider than the confidence interval, for a given  $x^*$  and confidence level. This makes sense, since

- the prediction interval must take account of the tendency of  $y$  to fluctuate from its mean value

## CI for $E(y)$ vs. PI for $y$ - differences

A prediction interval is similar in spirit to a confidence interval, except that

- the prediction interval is designed to cover a “moving target”, the random future value of  $y$
- the confidence interval is designed to cover the “fixed target”, the average (expected) value of  $y$ ,  $E(y)$ ,

Although both are centered at  $\hat{y}$ , the prediction interval is wider than the confidence interval, for a given  $x^*$  and confidence level. This makes sense, since

- the prediction interval must take account of the tendency of  $y$  to fluctuate from its mean value
- the confidence interval simply needs to account for the uncertainty in estimating the mean value
