Background on Compositional Data

UBIQUITY OF COMPOSITIONAL DATA

Compositional:Relating to parts of some wholeProportionsProportionsParts per millionX+Y+Z=kPercentagesAnd all Positive

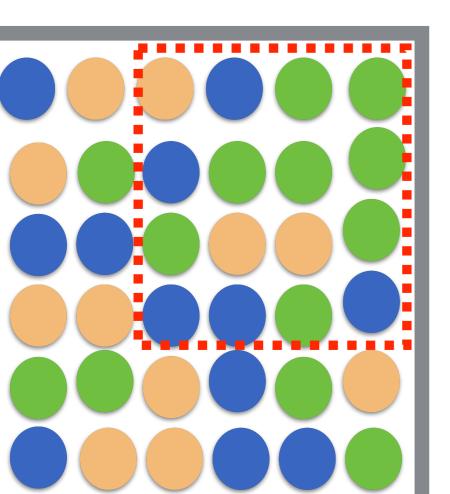

RELATIVE DATA

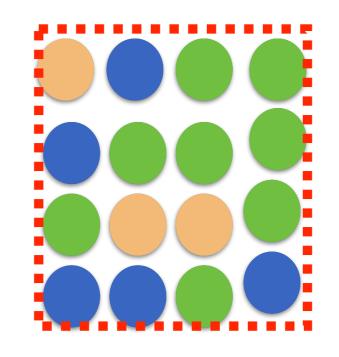

Simple Examples

- Does hongite have more calcium than struvite? (e.g., parts per million)
- Have I been spending more of my day in the bathroom since I ate that sandwich? (e.g., percentage of your day)
- Does my cow produce higher protein milk when I feed her that sandwich? (*e.g.*, proportion of calories from protein)

UBIQUITY OF COMPOSITIONAL DATA COUNTS!

UBIQUITY OF COMPOSITIONAL DATA COUNTS!

Examples

- Abundance Quantification by High Throughout Sequencing
 - Microbiome Composition (e.g., counts of 16s gene)
 - Gene expression analysis (e.g., RNA-seq)
- Abundance Quantification by Flow Cytometry
- Proportion of observed mice that go on to develop a disease?
- Population of North Carolina that is pro-Trump? (e.g., polling results)

The Shape of Compositional Data (Microbiome Example)

compositional data: usual representation

definition: $\mathbf{x} = [x_1, x_2, \dots, x_D]$ is a *D*-part composition

$$\begin{cases} x_i > 0, & \text{for all } i = 1, ..., D\\ \sum_{i=1}^{D} x_i = \kappa \quad (\text{constant}) \end{cases}$$

 $\begin{array}{ll} \kappa = 1 & \Longleftrightarrow \text{ measurements in parts per unit} \\ \kappa = 100 & \Longleftrightarrow \text{ measurements in percent} \\ \text{other frequent units: ppm, ppb, ...} \end{array}$

a composition is the representative in the simplex of equivalent vectors with strictly positive components

a **subcomposition** \mathbf{x}_s with *s* parts is obtained as the closure of a subvector $[x_{i_1}, x_{i_2}, \dots, x_{i_s}]$ of \mathbf{x}

requirements for a proper analysis

- scale invariance: the analysis should not depend on the closure constant κ; proportional positive vectors are equivalent as compositions
- permutation invariance: the order of the parts should be irrelevant
- subcompositional coherence: studies performed on subcompositions should not stand in contradiction with those performed on the full composition

presentation

final comments

why a new geometry on the simplex?

in real space \mathbb{R}^D we **add** vectors, we **multiply** them by a constant, we look for **orthogonality** between vectors, we look for **distances** between points, ...

possible because \mathbb{R}^D is a Euclidean vector space

BUT the usual Euclidean geometry in real space is not a proper geometry for compositional data because

- results might not be in the simplex when we add compositional vectors, multiply them by a constant, or compute confidence regions
- Euclidean differences are not always reasonable: from 0.05% to 0.10% the amount is doubled; from 50.05% to 50.10% the increase is negligible

closure of $\mathbf{z} = [z_1, z_2, \dots, z_D] \in \mathbb{R}^D_+$, with closure constant $= \kappa$

$$\mathcal{C}\left[\mathbf{z}\right] = \left[\frac{\kappa \cdot z_1}{\sum_{i=1}^{D} z_i}, \frac{\kappa \cdot z_2}{\sum_{i=1}^{D} z_i}, \cdots, \frac{\kappa \cdot z_D}{\sum_{i=1}^{D} z_i}\right]$$

 $\mathcal{C}\left[\boldsymbol{z}\right]$ is the representative of \boldsymbol{z} in $\mathcal{S}^{\mathcal{D}}$

perturbation of $\mathbf{x} \in \mathcal{S}^{D}$ by $\mathbf{y} \in \mathcal{S}^{D}$

$$\mathbf{X} \oplus \mathbf{y} = \mathcal{C} \left[x_1 y_1, x_2 y_2, \dots, x_D y_D \right]$$

powering of $\mathbf{x} \in \mathcal{S}^D$ by $\alpha \in \mathbb{R}$

$$\alpha \odot \mathbf{X} = \mathcal{C}\left[\mathbf{X}_{1}^{\alpha}, \mathbf{X}_{2}^{\alpha}, \dots, \mathbf{X}_{D}^{\alpha}\right]$$

interpretation of perturbation and powering

left: perturbation of initial compositions (\circ) by **p** = [0.1, 0.1, 0.8] resulting in compositions (\star)

right: powering of compositions (*) by $\alpha = 0.2$ resulting in compositions (°)

presentation	CoDa ○	historical remarks	sample space	Aitchison geometry	final comments
comme	ents				

- closure = projection of a point in \mathbb{R}^{D}_{+} on \mathcal{S}^{D}
- points on a ray are projected onto the same point
 - a ray in \mathbb{R}^{D}_{+} is an equivalence class
 - the point on \mathcal{S}^{D} is a representative of the class
 - a generalization to other representatives is possible

• for $\mathbf{z} \in \mathbb{R}^{D}_{+}$ and $\mathbf{x} \in \mathcal{S}^{D}$, $\mathbf{x} \oplus (\alpha \odot \mathbf{z}) = \mathbf{x} \oplus (\alpha \odot \mathcal{C} [\mathbf{z}])$

vector space structure of $(\mathcal{S}^{\mathcal{D}}, \oplus, \odot)$

• commutative group structure of $(\mathcal{S}^{D}, \oplus)$

• commutativity: $\mathbf{x} \oplus \mathbf{y} = \mathbf{y} \oplus \mathbf{x}$ • associativity: $(\mathbf{x} \oplus \mathbf{y}) \oplus \mathbf{z} = \mathbf{x} \oplus (\mathbf{y} \oplus \mathbf{z})$ • neutral element: $\mathbf{e} = \mathcal{C} [1, 1, \dots, 1] = \text{barycentre of } \mathcal{S}^{\mathcal{D}}$ • inverse of \mathbf{x} : $\mathbf{x}^{-1} = \mathcal{C} \left[x_1^{-1}, x_2^{-1}, \dots, x_D^{-1} \right]$ $\Rightarrow \mathbf{x} \oplus \mathbf{x}^{-1} = \mathbf{e}$ and $\mathbf{x} \oplus \mathbf{y}^{-1} = \mathbf{x} \oplus \mathbf{y}$

properties of powering

associativity: α ⊙ (β ⊙ x) = (α ⋅ β) ⊙ x;
 distributivity 1: α ⊙ (x ⊕ y) = (α ⊙ x) ⊕ (α ⊙ y)
 distributivity 2: (α + β) ⊙ x = (α ⊙ x) ⊕ (β ⊙ x)
 neutral element: 1 ⊙ x = x

complete inner product space structure

d

inner product :
$$\langle \mathbf{x}, \mathbf{y} \rangle_{a} = \frac{1}{2D} \sum_{i=1}^{D} \sum_{j=1}^{D} \ln \frac{x_{i}}{x_{j}} \ln \frac{y_{i}}{y_{j}}, \quad \mathbf{x}, \mathbf{y} \in \mathcal{S}^{D}$$

$$\begin{aligned} \mathbf{norm} : \quad \|\mathbf{x}\|_{a} &= \sqrt{\frac{1}{2D}\sum_{i=1}^{D}\sum_{j=1}^{D}\left(\ln\frac{x_{j}}{x_{j}}\right)^{2}}, \quad \mathbf{x} \in \mathcal{S}^{D} \\ \end{aligned}$$
$$\begin{aligned} \text{listance} : \quad d_{a}(\mathbf{x}, \mathbf{y}) &= \sqrt{\frac{1}{2D}\sum_{i=1}^{D}\sum_{j=1}^{D}\left(\ln\frac{x_{i}}{x_{j}} - \ln\frac{y_{i}}{y_{j}}\right)^{2}}, \quad \mathbf{x}, \mathbf{y} \in \mathcal{S}^{D} \end{aligned}$$

Aitchison geometry on the simplex

 $(\mathcal{S}^{D}, \oplus, \odot)$ is a (D-1)-dim. Euclidean space

properties of the Aitchison geometry

distance and perturbation: $d_a(\mathbf{p} \oplus \mathbf{x}, \mathbf{p} \oplus \mathbf{y}) = d_a(\mathbf{x}, \mathbf{y})$

distance and powering: $d_a(\alpha \odot \mathbf{x}, \alpha \odot \mathbf{y}) = |\alpha| d_a(\mathbf{x}, \mathbf{y})$

compositional lines: $\mathbf{y} = \mathbf{x}_0 \oplus (\alpha \odot \mathbf{x})$ (\mathbf{x}_0 = starting point, \mathbf{x} = leading vector)

orthogonal lines: $y_1 = x_0 \oplus (\alpha_1 \odot x_1), y_2 = x_0 \oplus (\alpha_2 \odot x_2),$

$$\mathbf{y_1} \perp \mathbf{y_2} \iff \langle \mathbf{x_1}, \mathbf{x_2} \rangle_a = \mathbf{0}$$

(the inner product of the leading vectors is zero) parallel lines: $\mathbf{y_1} = \mathbf{x_0} \oplus (\alpha \odot \mathbf{x}) \parallel \mathbf{y_2} = \mathbf{p} \oplus \mathbf{x_0} \oplus (\alpha \odot \mathbf{x})$

ellipses and shifted segments

ロ > < 個 > < 目 > < 目 > < 目 > < 回 > < < の へ ()

advantages of complete inner product spaces

- orthonormal basis can be constructed: $\{e_1, \ldots, e_{D-1}\}$
- coordinates obey the rules of real Euclidean space:

$$\mathbf{x} \in S^{D} \Rightarrow \mathbf{y} = [y_{1}, \dots, y_{D-1}] \in \mathbb{R}^{D-1}$$
, with $y_{i} = \langle \mathbf{x}, \mathbf{e}_{i} \rangle_{a}$

- standard methods can be directly applied to coordinates
- expressing results as compositions is easy:

if $h : S^D \mapsto \mathbb{R}^{D-1}$ assigns to each $\mathbf{x} \in S^D$ its coordinates, i.e. $h(\mathbf{x}) = \mathbf{y}$, then

$$h^{-1}(\mathbf{y}) = \mathbf{x} = \bigoplus_{i=1}^{D-1} y_i \odot \mathbf{e}_i$$

PRINCIPLE OF WORKING ON COORDINATES

presentation	CoDa ○	historical remarks	sample space	Aitchison geometry	final comments ○●○○
conclu	sions				

- the Aitchison geometry of the simplex offers a powerful tool to analyse CoDa
- the geometry is apparently complex, but it is completely equivalent to standard Euclidean geometry in real space
- the key is to use a proper representation in coordinates
